Abstract

The baryon to photon ratio in the present Universe is very accurately measured to be 6.19×10^{-10} . We study the possible origin of this baryon asymmetry in the neutrino sector through the generic mechanism of baryogenesis through leptogenesis. We consider both type I and type II seesaw origin of neutrino masses within the framework of left right symmetric models (LRSM). Using the latest best fit global neutrino oscillation data and assuming the Dirac neutrino mass matrix to be either charged lepton (CL) or up quark (UQ) type, we compute the predictions for baryon to photon ratio keeping the lightest active neutrino mass eigenstate a free parameter for both normal and inverted hierarchical cases. We show that in inverted hierarchical scenario with type I seesaw, observed baryon asymmetry can not be generated for both CL and UQ type Dirac neutrino mass matrices. We also study the predictions for baryon asymmetry when the neutrino masses arise from a combination of both type I and type II (with one of them dominant at a time) and show that observed baryon asymmetry can be generated within these models upto certain exceptions.

I. INTRODUCTION

Recent neutrino oscillation experiments have provided significant amount of evidence which confirms the existence of the non-zero yet tiny neutrino masses [1]. We know that the smallness of three Standard Model neutrino masses can be naturally explained via seesaw mechanism. In general, such seesaw mechanism can be of three types : type I [2], type II [3] and type III [4]. All these mechanisms involve the inclusion of additional fermionic or scalar fields to generate tiny neutrino masses at tree level. Although these seesaw models can naturally explain the smallness of neutrino mass compared to the electroweak scale, we are still far away from understanding the origin of neutrino mass hierarchies as suggested by experiments. Recent neutrino oscillation experiments T2K [5], Double ChooZ [6], Daya-Bay [7] and RENO [8] have not only made the earlier predictions for neutrino parameters more precise, but also predicted non-zero value of the reactor mixing angle θ_{13} . The latest global fit value for 3σ range of neutrino oscillation parameters [9] are as follows:

$$\begin{aligned}
\Delta m_{21}^2 &= (7.00 - 8.09) \times 10^{-5} \text{ eV}^2 \\
\Delta m_{31}^2 \text{ (NH)} &= (2.27 - 2.69) \times 10^{-3} \text{ eV}^2 \\
\Delta m_{23}^2 \text{ (IH)} &= (2.24 - 2.65) \times 10^{-3} \text{ eV}^2 \\
\sin^2 \theta_{12} &= 0.27 - 0.34 \\
\sin^2 \theta_{23} &= 0.34 - 0.67 \\
\sin^2 \theta_{13} &= 0.016 - 0.030 \\
\delta_{CP} &= 0 - 2\pi
\end{aligned} \tag{1}$$

where NH and IH refers to normal and inverted hierarchy respectively.

The above recent data have positive evidence for non-zero θ_{13} as well, which was earlier thought to be zero or negligibly small. This has led to a great deal of activities in neutrino model building [10, 11]. These frameworks which predict non-zero θ_{13} may also shed light on the Dirac CP violating phase which is still unknown (and could have remained unknown if θ_{13} were exactly zero). Apart from predicting the correct neutrino oscillation data as well as the Dirac CP phase, the nature of neutrino mass hierarchy is also an important yet unresolved issue. Understanding the correct nature of hierarchy can also have non-trivial

relevance in the production of matter antimatter asymmetry (or baryon asymmetry) and other relevant cosmology issues. The observed baryon asymmetry in the Universe is encoded in the baryon to photon ratio measured by dedicated cosmology experiments like Wilkinson Mass Anisotropy Probe (WMAP) among others. The baryon to photon ratio in nine year WMAP data [12] is found to be

$$Y_B \simeq (6.19 \pm 0.14) \times 10^{-10} \quad (2)$$

Leptogenesis is a novel mechanism to generate this observed baryon asymmetry in the Universe by generating an asymmetry in the lepton sector first which is later converted into baryon asymmetry through electroweak sphaleron transitions [13]. As pointed out by Fukugita and Yanagida [14], the out of equilibrium and CP violating decay of heavy Majorana neutrinos provides a natural way to create the required lepton asymmetry. The novel feature of this mechanism is the way it relates two of the most widely problems in physics : the origin of neutrino mass and the origin of matter-antimatter asymmetry.

In view of above, the present work is planned to carry out a study of baryogenesis through leptogenesis in neutrino mass models with normal and inverted hierarchical neutrino masses within the framework of generic left-right symmetric models (LRSM) [15]. Such a work was done recently in [16] where the viability of several models were studied by fitting their predictions to the best fit neutrino oscillation data in the presence of both type I and type II seesaw. In this present work, we scan the parameter space of the same sets of models by calculating the baryon asymmetry and comparing with the experimental data. We parametrize the neutrino mass matrix using global fit neutrino oscillation data. We then keep the lightest active neutrino mass eigenstate as a free parameter and find out the allowed range of its mass for which correct baryon asymmetry can be generated. This calculation is performed by considering either type I or type II seesaw at a time and taking the Dirac neutrino mass matrix to be either CL type or UQ type. We then consider the contribution of both type I and type II seesaw terms to the neutrino mass with one of them dominating at a time. The dominating seesaw term is then used to find out the right-handed Majorana neutrino mass matrix by assuming two different types of Dirac neutrino mass matrices (CL and UQ type). Fixing the dominating seesaw term in this way, the other seesaw term is allowed to vary and prediction for baryon asymmetry is calculated for different combinations of Majorana neutrino phases $\pi/6, \pi/4, \pi/3, \pi/2$. We note that the variation of Majorana

phases and the strength of the non-leading seesaw term not only changes the predictions for baryon to photon ratio but also leads to a sign flip (which would correspond to an antimatter dominated Universe) in some cases.

This paper is organized as follows: in section II we discuss the methodology of type I and type II seesaw mechanism in generic LRSM. In section III, we outline the details of computing baryon asymmetry in LRSM. In section IV we discuss our numerical analysis and results. We then finally conclude in section V.

II. SEESAW IN LRSM

Type I seesaw framework is the simplest possible seesaw mechanism and can arise in simple extensions of the standard model by three right handed neutrinos. There is also another type of non-canonical seesaw formula (known as type-II seesaw formula)[3] where a left-handed Higgs triplet Δ_L picks up a vacuum expectation value (vev). This is possible both in the minimal extension of the standard model by Δ_L or in other well motivated extensions like left-right symmetric models (LRSM) [15]. The seesaw formula in LRSM can be written as

$$m_{LL} = m_{LL}^{II} + m_{LL}^I \quad (3)$$

where the usual type I seesaw formula is given by the expression,

$$m_{LL}^I = -m_{LR}M_{RR}^{-1}m_{LR}^T. \quad (4)$$

Here m_{LR} is the Dirac neutrino mass matrix. The above seesaw formula with both type I and type II contributions can naturally arise in extension of standard model with three right handed neutrinos and one copy of Δ_L . However, we will use this formula in the framework of LRSM where M_{RR} arises naturally as a result of parity breaking at high energy and both the type I and type II terms can be written in terms of M_{RR} . In LRSM with Higgs triplets, M_{RR} can be expressed as $M_{RR} = v_R f_R$ with v_R being the vev of the right handed triplet Higgs field Δ_R imparting Majorana masses to the right-handed neutrinos and f_R is the corresponding Yukawa coupling. The first term m_{LL}^{II} in equation (3) is due to the vev of $SU(2)_L$ Higgs triplet. Thus, $m_{LL}^{II} = f_L v_L$ and $M_{RR} = f_R v_R$, where $v_{L,R}$ denote the vev's and $f_{L,R}$ are symmetric 3×3 matrices. The left-right symmetry demands $f_R = f_L = f$. The

induced vev for the left-handed triplet v_L can be shown for generic LRSM to be

$$v_L = \gamma \frac{M_W^2}{v_R}$$

with $M_W \sim 80.4$ GeV being the weak boson mass such that

$$|v_L| \ll M_W \ll |v_R|$$

In general γ is a function of various couplings in the scalar potential of generic LRSM and without any fine tuning γ is expected to be of the order unity ($\gamma \sim 1$). type-II seesaw formula in equation (3) can now be expressed as

$$m_{LL} = \gamma(M_W/v_R)^2 M_{RR} - m_{LR} M_{RR}^{-1} m_{LR}^T \quad (5)$$

With above seesaw formula (5), the neutrino mass matrices are constructed by considering contributions from both type I and type II terms. The choice of v_R however, remains ambiguous in the literature where different choices of v_R are made according to convenience [17–21]. However, in this present work we will always take v_R as $v_R = \gamma \frac{M_W^2}{v_L} \simeq \gamma \times 10^{15}$ GeV [20, 21]. It is worth mentioning that, here $SU(2)_R \times U(1)_{B-L}$ gauge symmetry breaking scale (as in generic LRSM) v_R is the same as the scale of parity breaking [17]. Using this form of v_R , the seesaw formula (5) becomes

$$m_{LL} = \gamma \left(\frac{M_W}{\gamma \times 10^{15}} \right)^2 M_{RR} - m_{LR} M_{RR}^{-1} m_{LR}^T \quad (6)$$

Quantitatively, either of the two terms on the right hand side of equation (6) can be dominant or both the terms can be equally dominant. However, for generic choices of symmetry breaking scales (mentioned above) as well as the Dirac neutrino mass matrices (generically to be of same order as corresponding charged lepton masses), both type I and type II term can be equally dominant only when the dimensionless parameter γ is fine tuned to be very small. We check this by equating both the terms to the best fit value of m_{LL} . We skip such a fine-tuned case here and consider two other possible cases in our work: one in which type I term dominates whereas type II term is present as a small perturbation and the other in which type II term dominates with type I term as a small perturbation.

A. Case I: Dominating Type I Seesaw

In this case, the second term in the equation (6) gives the leading contribution to m_{LL} and hence we compute the right-handed neutrino mass matrix M_{RR} by using the inverse

type I seesaw formula $M_{RR} = m_{LR}^T m_{LL}^{-1} m_{LR}$ where we use the best fit m_{LL} and generic m_{LR} as will be shown in the section [IV](#). Here we hold M_{RR} fixed, so the first term in equation [\(6\)](#) is dependent on the value of γ while second term is fixed. For $\gamma \sim 1$, the first term has minimum contribution whereas for smaller values of γ , the contribution of the type II term will increase. We vary the dimensionless parameter γ from 0.0001 to 1.0 and check the survivability of neutrino mass models with contributions from type I and type II terms.

B. Case II: Dominating Type II seesaw

This is the case where the first term in the equation [\(6\)](#) gives the leading contribution to m_{LL} . This scenario within grand unified models like $SO(10)$ have been discussed in [\[22\]](#). In this case, we compute M_{RR}/γ from the inverse type II seesaw formula

$$\frac{M_{RR}}{\gamma} = \left(\frac{1 \times 10^{15}}{M_W} \right)^2 m_{LL} \quad (7)$$

It should be noted that here we are keeping M_{RR}/γ constant instead of just M_{RR} as in the case I. Thus, although the first term in equation [\(6\)](#) remains constant, the second term varies as we vary γ and have the minimal contribution for $\gamma \sim 1$. Similar to the case I, here also we vary γ between 0.0001 and 1.0 and calculate the predictions for baryon asymmetry. The details of both these case will be presented in details in section [IV](#)

III. LEPTOGENESIS IN LRSM

Study of Leptogenesis in LRSM has received lots of attention in last two decades and a large number of works dedicated to this topic can be found in the literature. Here we closely follow the notations of [\[21\]](#) to carry out our analysis.

For the calculation of baryon asymmetry, we go to the basis where the right handed Majorana neutrino mass matrix is diagonal

$$U_R^* M_{RR} U_R^\dagger = \text{diag}(M_1, M_2, M_3)$$

In this diagonal M_{RR} basis, the Dirac neutrino mass matrix also changes to

$$m_{LR} = m_{LR}^d U_R$$

FIG. 1: Predictions for baryon to photon ratio as a function of lightest active neutrino mass eigenstate (in eV) for CL type m_{LR}

where m_{LR}^d is the assumed choice of the Dirac neutrino mass matrix in our calculation which is either CL or UQ type diagonal matrix. The lepton asymmetry arising from the decays of the lightest right handed Majorana neutrino $N_1 \rightarrow \Phi L^c$ and $N_1 \rightarrow \Phi^\dagger L$:

$$\begin{aligned} \epsilon &= \frac{\Gamma(N_1 \rightarrow \Phi L^c) - \Gamma(N_1 \rightarrow \Phi^\dagger L)}{\Gamma(N_1 \rightarrow \Phi L^c) + \Gamma(N_1 \rightarrow \Phi^\dagger L)} \\ &= \frac{1}{8\pi v^2} \frac{1}{(m_{LR}^\dagger m_{LR})_{11}} \sum_{j=2,3} \text{Im}(m_{LR}^\dagger m_{LR})_{1j}^2 f(M_j^2/M_1^2) \end{aligned} \quad (8)$$

where $v = 174$ GeV is the vev of the Higgs bidoublets responsible for breaking the electroweak symmetry and the function $f(x) = -\frac{3}{2\sqrt{x}}$ for $x \gg 1$. After determining the lepton asymmetry ϵ , the corresponding baryon asymmetry can be obtained by

$$Y_B = c\kappa \frac{\epsilon}{g_*} \quad (9)$$

through electroweak sphaleron processes [13]. Here the factor c is measure of the fraction of lepton asymmetry being converted into baryon asymmetry and is approximately equal to -0.55 . κ is the dilution factor due to wash-out process which erase the produced asymmetry

FIG. 2: Predictions for baryon to photon ratio as a function of lightest active neutrino mass eigenstate (in eV) for UQ type m_{LR}

and can be parametrized as [23]

$$\begin{aligned}
 -\kappa &\simeq \sqrt{0.1K} \exp[-4/(3(0.1K)^{0.25})], \quad \text{for } K \geq 10^6 \\
 &\simeq \frac{0.3}{K(\ln K)^{0.6}}, \quad \text{for } 10 \leq K \leq 10^6 \\
 &\simeq \frac{1}{2\sqrt{K^2 + 9}}, \quad \text{for } 0 \leq K \leq 10.
 \end{aligned} \tag{10}$$

where K is given as

$$K = \frac{\Gamma_1}{H(T = M_1)} = \frac{(m_{LR}^\dagger m_{LR}) M_1}{8\pi v^2} \frac{M_{Pl}}{1.66\sqrt{g_*} M_1^2}$$

Here Γ_1 is the decay width of N_1 and $H(T = M_1)$ is the Hubble constant at temperature $T = M_1$. The factor g_* is the effective number of relativistic degrees of freedom at $T = M_1$ and is approximately 110.

FIG. 3: Variation of baryon to photon ratio with γ and Majorana phases for CL type m_{LR} and dominant type I seesaw with normal hierarchy

IV. NUMERICAL ANALYSIS AND RESULTS

For the purpose of numerical analysis we parametrize the neutrino mixing matrix as

$$U_L = \begin{pmatrix} c_{12}c_{13} & s_{12}c_{13} & s_{13}e^{-i\delta} \\ -s_{12}c_{23} - c_{12}s_{23}s_{13}e^{i\delta} & c_{12}c_{23} - s_{12}s_{23}s_{13}e^{i\delta} & s_{23}c_{13} \\ s_{12}s_{23} - c_{12}c_{23}s_{13}e^{i\delta} & -c_{12}s_{23} - s_{12}c_{23}s_{13}e^{i\delta} & c_{23}c_{13} \end{pmatrix} \text{diag}(1, e^{i\alpha}, e^{i(\beta+\delta)}) \quad (11)$$

where $c_{ij} = \cos \theta_{ij}$, $s_{ij} = \sin \theta_{ij}$. δ is the Dirac CP phase and α, β are the Majorana phases. Since we know only the two mass squared differences for the active neutrinos, we consider a hierarchical pattern of neutrino masses where the heavier mass eigenstates are of the order of the mass squared differences, whereas the lightest one can be much lighter than the other two. We take the best fit central values of the mixing angles and take the Dirac CP phase to be π [24].

After parameterizing the neutrino mass matrix using oscillation data, we consider the two cases I and II mentioned in the previous section one by one. First, we consider the case I i.e., type I dominance and calculate the right-handed Majorana neutrino matrix M_{RR}

FIG. 4: Variation of baryon to photon ratio with γ and Majorana phases for CL type m_{LR} and dominant type II seesaw with normal hierarchy

using the inverse type I seesaw formula

$$M_{RR} = m_{LR}^T m_{LL}^{-1} m_{LR}, \quad (12)$$

To calculate the M_{RR} for each case, we need to have the Dirac neutrino mass matrix (m_{LR}). We take the Dirac neutrino mass matrix m_{LR} to be diagonal with either charged lepton mass structure or up quark mass structure. The general form of Dirac neutrino mass matrix is

$$m_{LR}^{(0)} = \begin{pmatrix} \lambda^m & 0 & 0 \\ 0 & \lambda^n & 0 \\ 0 & 0 & 1 \end{pmatrix} m_f \quad (13)$$

where m_f corresponds to $m_\tau \tan \beta$ for $(m, n) = (6, 2)$, $\tan \beta = 40$ in case of charged lepton and m_t for $(m, n) = (8, 4)$ in the case of up-quarks [25, 26]. $\lambda = 0.22$ is the standard Wolfenstein parameter. It should be noted that such a diagonal form of Dirac neutrino mass matrix can be naturally achieved by applying additional flavor symmetries. A possible abelian gauge symmetry that can constrain the Dirac neutrino mass matrix to the diagonal form was outlined recently in one of our works (first reference in [16]). Now, using m_{LR} in the

FIG. 5: Variation of baryon to photon ratio with γ and Majorana phases for CL type m_{LR} and dominant type II seesaw with inverted hierarchy

inverse type I seesaw formula above, we calculate M_{RR} . For case II that is type II seesaw dominating scenario, we calculate M_{RR} by using the type II seesaw formula for $\gamma = 1.0$. After calculating M_{RR} for both type I and type II seesaw dominating cases, we calculate the predictions for baryon asymmetry by varying the lightest active neutrino mass eigenstates for both types of neutrino mass hierarchies (Normal and Inverted) as well as both types of Dirac neutrino mass matrices (CL and UQ). The results are shown in figure 1 and 2. We notice that, for the entire range of lightest active neutrino mass eigenstate we scan through, inverted hierarchy with type I seesaw domination do not give rise to the observed baryon asymmetry for both CL and UQ type Dirac neutrino mass matrices. Whereas, for normal hierarchy with either type I or type II seesaw as well as inverted hierarchy with type II seesaw are found to produce the observed baryon asymmetry for certain ranges of lightest active neutrino masses as seen from figure 1 and 2.

After calculating the baryon asymmetry for type I seesaw and type II seesaw separately, we consider the contribution of both type I and type II seesaw terms to the neutrino mass by considering one of them dominating at a time. The contribution of the non-leading

FIG. 6: Variation of baryon to photon ratio with γ and Majorana phases for UQ type m_{LR} and dominant type I seesaw with normal hierarchy

seesaw term can be adjusted by varying the dimensionless parameter γ with minimum non-leading contribution for $\gamma \sim 1$. We vary this dimensionless parameter γ from 0.0001 to 1.0 and check the variations in the predictions for baryon asymmetry. We do this exercise for different Majorana phases $\alpha = \beta = \pi/6, \pi/4, \pi/3, \pi/2$ as shown in the figures 3, 4, 5, 6, 7, 8. These figures show that the variations of Majorana phases as well as γ can not only change the predictions for baryon asymmetry from the observed value but also can give rise to a flip in sign which would correspond to a Universe with more antimatter than matter.

We observe that, in the presence of both type I and type II seesaw contribution, only the inverted hierarchical scenario with UQ type Dirac neutrino mass matrix gives rise to correct baryon asymmetry provided the Majorana phases are close to $\pi/6$. Thus, we can discriminate between several models by comparing their predictions with the observed baryon asymmetry. From such an analysis, we can also constrain the parameters like Majorana phases, which are presently unconstrained from neutrino experiments.

FIG. 7: Variation of baryon to photon ratio with γ and Majorana phases for UQ type m_{LR} and dominant type II seesaw with normal hierarchy

V. CONCLUSION

We have studied the possibility of producing the observed baryon asymmetry in the Universe within the framework of generic left-right symmetric models by considering both types of hierarchies (normal and inverted) and two types of Dirac neutrino mass matrices: charged lepton type and up quark type. In generic LRSM, neutrino mass can get contributions from both type I as well as type II seesaw terms. We consider two possible cases: one in which type I seesaw dominates and the other in which type II seesaw dominates.

We use the generic parametrization of neutrino mixing matrix and find the numerical value of these parameters using the global fit neutrino oscillation data. We consider the heavier mass eigenstates of active neutrinos to be of the order of measured mass squared differences and keep the lightest mass eigenstate as a free parameter. We then compute the predictions for baryon to photon ratio by considering either type I or type II seesaw terms for both the types of hierarchies as well as both CL and UQ type Dirac neutrino mass matrices. We show that inverted hierarchical models with type I seesaw are disfavored as

FIG. 8: Variation of baryon to photon ratio with γ and Majorana phases for UQ type m_{LR} and dominant type II seesaw with inverted hierarchy

their predicted baryon asymmetry falls below the observed value by around two orders of magnitudes.

We then keep the dominating seesaw term fixed in the seesaw formula and vary the other term by varying the dimensionless parameter γ . We then calculate the predictions for baryon asymmetry for different values of γ as well as four different Majorana phases $\pi/6, \pi/4, \pi/3, \pi/2$. We show that for UQ type Dirac mass matrices and inverted hierarchy, Majorana phase of $\pi/6$ is more favorable. For the case of normal hierarchy, a combination of type I and type II seesaw do not give rise to the observed baryon asymmetry for all the Majorana phases we have considered. However, type I or type II seesaw separately can give rise to the observed baryon asymmetry in these models as can be seen from figure 1, 2.

In view of above, the neutrino mass models considered in our study can survive in nature and produce the observed baryon asymmetry within the framework of type I and type II seesaw mechanism. Inverted hierarchy with type I seesaw was found to be disfavored in our analysis as it falls short of the observed baryon asymmetry by two orders of magnitudes. Whereas, normal hierarchy can give rise to the observed baryon asymmetry for both type

I and type II seesaw separately and both CL and UQ type Dirac neutrino mass matrices. However, in the presence of both type I and type II seesaw (with one of them dominating at a time), most of the models included in our study are found to be disfavored except the inverted hierarchical case with type II seesaw dominance and UQ type Dirac neutrino mass matrix. More precise data from neutrino oscillation experiments as well as cosmology should be able to reduce the number of available possibilities presented in our analysis.
